

The Digestive Process

The digestive system

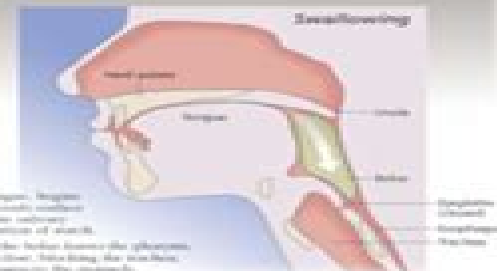

The digestive system, or gastrointestinal tract, is essentially a muscular tube in which food is broken down into absorbable nutrients and eliminated as waste. Food enters the mouth, is chewed and swallowed, passes through the stomach and small intestine, is absorbed in the large intestine, and is eliminated as waste. The digestive system also stores undigested components until they are ready to be expelled at the end of the gastrointestinal tract.

Ingestion

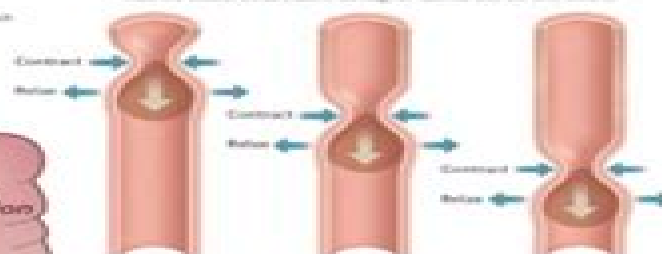

Chewing & swallowing

Chewing, the mechanical action of the mouth and tongue, begins the breakdown of solid food. This greatly increases food's surface area and exposes the food to the action of enzymes in the salivary glands. Saliva softens the food and begins the digestion of starch. The mixture of food and saliva is called a *bolus*. In the bolus, the pharynx, the esophagus, a flap-like valve, and the vocal cord contract, forcing the bolus forward, where it moves down through the esophagus to the stomach.

Peristaltic action

Material is moved through the digestive system by a series of smooth muscle contractions called peristalsis. The muscle is relaxed at the material's entrance, while the muscle ahead contracts, forcing the material into the next section.

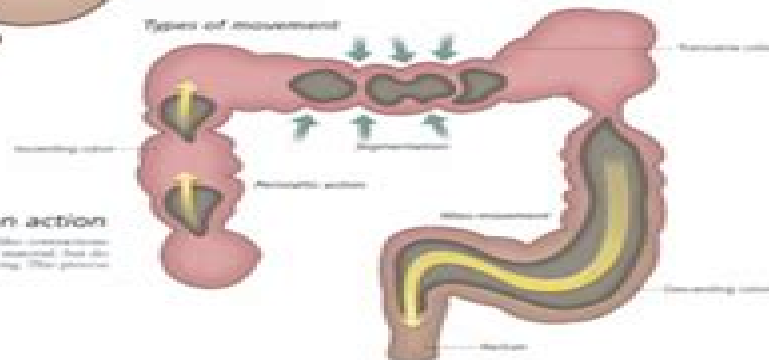

In the esophagus, material moves through the large intestine, where water and electrolytes are absorbed (dehydrated). This remaining mass is moved forward and upward (defecation).

Colonic movement

Movement through the large intestine is accomplished through the contractions of the longitudinal and circular muscles. Types of movement include peristaltic action, segmental action, and mass movement. Movement of food through the large intestine is slower than through the small intestine, allowing for reabsorption of water.

Types of movement

Segmentation action

In regular intervals, ring-like contractions (chase and pass the water material) pass the water (the material) along. This process is called segmentation.

Large intestine

Longitudinal muscle
Circular muscle
Segmental action

Muscle contractions begin to break up the material

Continuing muscle contractions produce further mixing

The waste material has been mixed, but not moved

Bile enters the small intestine and helps to break down fats into smaller particles. Pancreatic juice contains enzymes that digest proteins, breaking down fats, proteins and carbohydrates.
