Design of CMOS RFIC Ultra-Wideband Impulse Transmitters and Receivers Cam Nguyen, Meng Miao, 2017-03-21

This book presents the design of ultra wideband UWB impulse based transmitter and receiver frontends operating within the 3.1-10.6 GHz frequency band using CMOS radio frequency integrated circuits RFICs. CMOS RFICs are small, cheap, low power devices better suited for direct integration with digital ICs as compared to those using III-V compound semiconductor devices. CMOS RFICs are thus very attractive for RF systems and in fact the principal choice for commercial wireless markets. The book comprises seven chapters. The first chapter gives an introduction to UWB technology and outlines its suitability for high resolution sensing and high rate short range ad hoc networking and communications. The second chapter provides the basics of CMOS RFICs needed for the design of the UWB RFIC transmitter and receiver presented in this book. It includes the design fundamentals, lumped and distributed elements for RFIC layout, post layout simulation and measurement. The third chapter discusses the basics of UWB systems including UWB advantages and applications, signals, basic modulations, transmitter and receiver frontends and antennas. The fourth chapter addresses the design of UWB transmitters including an overview of basic components, design of pulse generator, BPSK modulator design and design of a UWB tunable transmitter. Chapter 5 presents the design of UWB receivers including the design of UWB low noise amplifiers, correlators and a UWB 1 receiver. Chapter 6 covers the design of a UWB uniplanar antenna. Finally a summary and conclusion is given in Chapter 7.

Analog VLSI Integration of Massive Parallel Signal Processing Systems Peter Kinget, Michiel Steyaert, 2013-06-29

When comparing conventional computing architectures to the architectures of biological neural systems, we find several striking differences. Conventional computers use a low number of high performance computing elements that are programmed with algorithms to perform tasks in a time sequenced way; they are very successful in administrative applications, in scientific simulations and in certain signal processing applications. However, the biological systems still significantly outperform conventional computers in perception tasks, sensory data processing and motory control. Biological systems use a completely different computing paradigm: a massive network of simple processors that are adaptively interconnected and operate in parallel. Exactly this massively parallel processing seems the key aspect to their success. On the other hand, the development of VLSI technologies provides us with technological means to implement very complicated systems on a silicon die. Especially analog VLSI circuits in standard digital technologies open the way for the implementation of massively parallel analog signal processing systems for sensory signal processing applications and for perception tasks. In chapter 1, the motivations behind the emergence of the analog VLSI of massively parallel systems is discussed in detail together with the capabilities and limitations of VLSI technologies and the required research and developments. Analog parallel signal processing drives the development of very compact, high speed and low power circuits. An important technological limitation is the reduction of the size of circuits and the improvement of the speed and power consumption.

International Conference on Computer Applications 2012 :: Volume 03 Kokula Krishna Hari K, *Analysis and Synthesis of MOS Translinear Circuits* Remco J. Wiegerink, 2012-12-06

This book has its roots in an idea first formulated by Barrie Gilbert in 1975. He showed how bipolar analog circuits can realize nonlinear and computational functions. This extended the analog art from linear to nonlinear applications, hence the name translinear circuits. Not only did this new principle enable marvellous signal processing functions to be accurately implemented, but also the circuits were simple and practical. The perennial problems of analog IC design, namely temperature sensitivity, processing spread, device nonlinearity, and parasitic capacitance, were solved to a large extent. Using the translinear principle in circuit design requires changing your point of view in two ways. First, the grossly nonlinear characteristic of transistors is viewed as an asset rather than as a harmful property. Second, no longer are the signals represented by voltages but by currents. In fact, the attendant voltage changes are distorted, but as they are very small, they are only of secondary interest. Understanding and analyzing a given translinear circuit is fairly straightforward. But what about the converse situation? Suppose you're given some nonlinear or computational function to implement. How to find a suitable translinear circuit realization? The general problem of analog circuit synthesis is a difficult one and is receiving much attention nowadays. Some years ago I had the opportunity to investigate methods for designing bipolar translinear circuits. It turned out that translinear networks have some unique topological properties. Using these properties, it was possible to establish heuristic synthesis procedures.

Analog IC Design Techniques for Nanopower Biomedical Signal Processing Chutham Sawigun, Wouter A. Serdijn, 2022-09-01. As the requirements for low power consumption and very small physical dimensions in portable, wearable, and implantable medical devices are calling for integrated circuit design techniques using MOSFETs operating in the subthreshold regime, this book first revisits some well-known circuit techniques that use CMOS devices biased in subthreshold in order to establish nanopower integrated circuit designs. Based on these findings, this book shows the development of a class AB current mode sample and hold circuit with an order of magnitude improvement in its figure of merit compared to other state-of-the-art designs. Also, the concepts and design procedures of 1 single branch

filters 2 follower integrator based lowpass filters and 3 modular transconductance reduction techniques for very low frequency filters are presented Finally to serve the requirement of a very large signal swing in an energy based action potential detector a nanopower class AB current mode analog multiplier is designed to handle input current amplitudes of more than 10 times the bias current of the multiplier circuit The invented filter circuits have been fabricated in a standard 0.18 CMOS process in order to verify our circuit concepts and design procedures Their experimental results are reported
