Model Uncertainties in Foundation Design Chong Tang, Kok-Kwang Phoon, 2021-03-16 Model Uncertainties in Foundation Design is unique in the compilation of the largest and the most diverse load test databases to date covering many foundation types shallow foundations spudcans driven piles drilled shafts rock sockets and helical piles and a wide range of ground conditions soil to soft rock All databases with names prefixed by NUS are available upon request This book presents a comprehensive evaluation of the model factor mean bias and coefficient of variation COV for ultimate and serviceability limit state based on these databases These statistics can be used directly for AASHTO LRFD calibration Besides load test databases performance databases for other geo structures and

their model factor statistics are provided Based on this extensive literature survey a practical three tier scheme for classifying the model uncertainty of geo structures according to the model factor mean and COV is proposed This empirically grounded scheme can underpin the calibration of resistance factors as a function of the degree of understanding a concept already adopted in the Canadian Highway Bridge Design Code and being considered for the new draft for Eurocode 7 Part 1 EN 1997 1 202x The helical pile research in Chapter 7 was recognised by the 2020 ASCE Norman Medal

Haimes, 1998 The goal of this effort is to assist the Virginia Department of Transportation VDOT in improving the comparison in planning of potential primary and secondary roadway improvement projects Historical projects that have been implemented or considered for implementation have been used as a case study data set Methods are proposed for estimating cost performance gain and crash risk reduction of future roadway projects with

the main focus being the presentation of trade offs among these criteria If in a particular case more accurate and or appropriate data is available for one or more of these criteria e g from a simulation study that has been performed then this information can easily be used to supplement or replace the estimations proposed here The project comparison instrument combines three major decision making attributes in project selection crash risk performance and project cost By quantifying these attributes across a number of proposed highway improvement projects projects can more readily be compared to one another and a more holistic view of potential projects is achieved This is an important step when choosing a portfolio of projects each year In order to compare projects attributes are quantified in the following manner for planning level decisions Crash risk reduction is calculated as the number of crashes avoided per year at the project site Particular roadway improvements are typically assumed to decrease the expected number of crashes by a statistically determined and pretabulated percentage Performance gain is quantified by the vehicle minutes of travel time avoided in the peak hour Finally cost is modeled as the sum of preliminary engineering right of way and construction costs Once the objectives are quantified they can be graphically displayed in a Project Comparison Chart Examples for applying this approach are given in the text and in the accompanying workbook
