Abstract: The understanding of the natural history and biology of lung cancer has been enhanced by studies into circulating tumor cells (CTCs). Fundamental and translational research, as well as clinical trials in the characterization and behavior of these cells, have constantly contributed to improving understanding within the domain of thoracic oncology. However, the use of these CTCs as prognostic and predictive biomarkers has not been adopted to the same extent as circulating free DNA (cf-DNA) in plasma, in the daily practice of thoracic oncologists. However, recent technological advances have firmly put the detection and characterization of CTCs in thoracic oncology back on the agenda, and have opened up perspectives for their routine clinical use. This review discusses the major advances of using CTCs in the domain of thoracic oncology, as well as the envisaged short- and long-term prospects.

1. Introduction

Liquid biopsy (LB) plays a major role in thoracic oncology [1,2]. A number of recent publications and developments within this domain testify to the increasing importance of LB. These studies concern not only fundamental translational and clinical research, but also technological advances [3–7]. They have provided a better understanding of the molecular and cellular mechanisms, the progression of lung cancer, and the treatment of patients. Among these studies, research into mutations in EGFR using plasma circulating free DNA (cf-DNA) have led to the use of LB in the clinical routine for patients with advanced stage or metastatic non-small cell lung carcinoma (NSCLC) [2,8–10]. This approach is now used in a large number of hospitals.

The number of detectable biological targets in an LB that are potentially accessible to treatment has increased, and future application of different biomarkers can be envisaged in the short-term [11]. The complexity of molecules for detection in the blood of patients with lung cancer has increased with advances in our understanding of the biology of the different components circulating in the blood. These components include free or complexed nucleic acids, microparticles including exosomes,

Molecular mechanisms of cellular stress responses in cancer and their therapeutic implications Megan Chircop, Daniel Speidel, 2015-03-06 In response to stress cells can activate a myriad of signalling pathways to bring about a specific cellular outcome including cell cycle arrest DNA repair senescence and apoptosis This response is pivotal for tumour suppression as all of these outcomes result in restriction of the growth and or elimination of damaged and pre malignant cells Thus a large number of anti cancer agents target specific components of stress response signalling pathways with the aim of causing tumour regression by stimulating cell death However the efficacy of these agents is often impaired due to mutations in genes that are involved in these stress responsive signalling pathways and instead the oncogenic potential of a cell is increased leading to the initiation and or progression of tumourigenesis Moreover these genetic defects can increase or contribute to resistance to chemotherapeutic agents and or radiotherapy Modulating the outcome of cellular stress responses towards cell death in tumour cells without affecting

surrounding normal cells is thus one of the ultimate aims in the development of new cancer therapeutics To achieve this aim a detailed understanding of cellular stress response pathways and their aberrations in cancer is required This Research topic aims to reflect the broadness and complexity of this important area of cancer research *Clinical Decision-Making Study Guide for Medical-Surgical Nursing - Revised Reprint* Donna D.
