Biological Soil Crusts: Spatio-temporal Development and Ecological Functions of Soil Surface Microbial Communities across Different Scales

Shubin Lan, David R. Elliott, Sonia Chamizo, Vincent John Martin, Noah Linus Felde, Andrew David Thomas, 2024-08-09

Biological soil crusts (biocrusts) are widely distributed throughout the world and cover approximately 12% of the terrestrial surface. Biocrusts are composed of cyanobacteria, algae, lichens, mosses, and a great diversity of other microorganisms which bind soil particles together to form a layer of biological soil matrix on the soil surface, typically of several millimetres thickness. They are important sites of regional and global microbial diversity and perform multiple ecological functions, multifunctionality. During the evolution of terrestrial life on earth, biocrusts are regarded as the main colonising photosynthetic organisms before the advent of vascular vegetation. They not only represent the early stages of terrestrial ecosystems but also facilitate the ecosystem's development and succession. Therefore, biocrusts are recognised as ecological engineers in the natural development of ecosystems and for the restoration of degraded terrestrial ecosystems. The development of biocrusts is highly heterogeneous, which is reflected on both temporal and spatial scales, and this heterogeneity is still clearly visible even in a small scale. However, up to now, only limited knowledge is acquired on biocrust temporal and spatial organisation. In particular, there still is a large knowledge gap regarding the various biocrust communities under different developmental states and their related physiological metabolisms and ecological functions. Therefore, in-depth studies of these issues will undoubtedly further promote our understanding of the heterogeneous development of biocrusts as well as their ecological multifunctionality in terrestrial ecosystems. The relevant contributions are expected to provide a scientific basis for the management of biocrusts and technology development, e.g. cyanobacteria-induced biocrust technology for ecological restoration and the promotion of soil health.

Mangrove Ecology, Silviculture and Conservation

Peter Saenger, 2013-06-29. Mangroves are a fascinating group of plants that occur on tropical and subtropical shorelines of all continents where they are exposed to saltwater inundation, low oxygen levels around their roots, high light and temperature conditions, and periodic tropical storms. Despite these harsh conditions, mangroves may form luxuriant forests which are of significant economic and environmental value throughout the world; they provide coastal protection and underpin fisheries and forestry operations as well as a range of other human activities. This book provides an up-to-date account of mangrove plants from around the world together with silvicultural and restoration techniques and the

management requirements of these communities to ensure their sustainability and conservation All aspects of mangroves and their conservation are critically re examined Those activities which threaten their ongoing survival are identified and suggestions are offered to minimise their effects on these significant plant communities
