

The Digestive Process

The digestive system

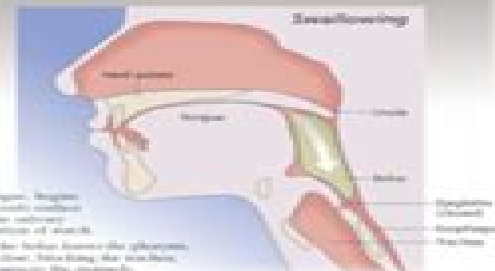

The digestive system, or gastrointestinal tract, is essentially a muscular tube in which food is broken down by the action of enzymes and chemical substances. Food enters the mouth, is chewed, and is propelled through a series of different accessory and absorptive components. Within these components, food is digested (broken down) by digestive enzymes and components that absorb it. The digestive system also stores undigested components until they are ready to be expelled at the end of the gastrointestinal tract.

Ingestion

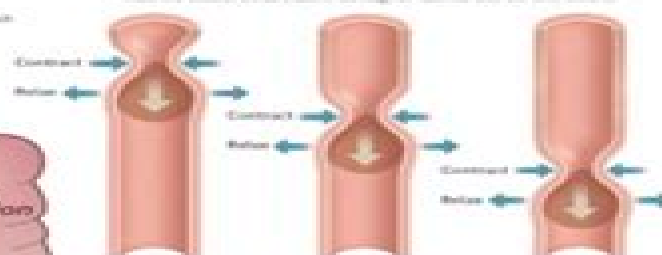

Chewing & swallowing

Chewing, the mechanical action of the mouth and tongue, begins the breakdown of solid food. This greatly increases food's surface area and exposes the food more fully to enzymes of the salivary glands. Saliva softens the food and begins the digestion of starch. The mixture of food and saliva is called a *bolus*. In the bolus, food is pushed by the tongue, a flap-like valve, and the vocal cord, forcing the bolus down the esophagus. Peristaltic action moves food through the esophagus to the stomach.

Peristaltic action

Material is moved through the digestive system by a series of muscle contractions called peristalsis. The muscle behind the material contracts, while the muscle ahead relaxes, thereby pushing the material into the next section.

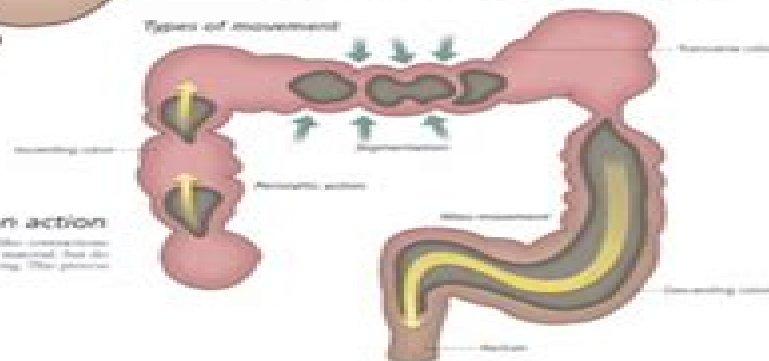

In the esophagus, material moves through the large intestine, where water and electrolytes are absorbed (reabsorbed). This reabsorption moves the material forward and upward (retrograde).

Colonic movement

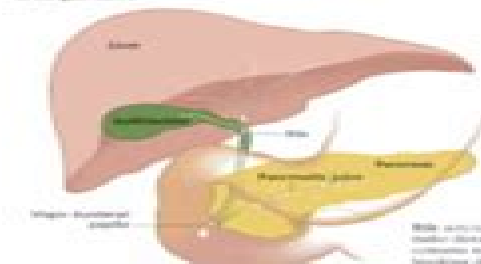

Movement through the large intestine is accomplished through the contractions of the longitudinal and circular muscles. Types of movement include peristaltic action, segmental action, and mass movement. Movement of food through the large intestine is slower than through the small intestine, allowing for reabsorption of water.

Types of movement

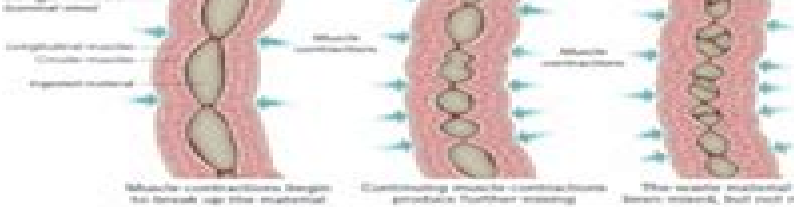

Segmentation action

In regular intervals, ring-like contractions (chase) and relax the water material, thus the water is called segmentation.

Bile enters the small intestine and helps to break down fatty acids. Bile is produced by the liver and stored in the gallbladder. Bile is released into the small intestine through the bile duct.
