

Cell Cycle: The process by which a cell grows and divides to produce two daughter cells. It is a highly regulated process that ensures the accurate transmission of genetic information.

Prokaryotic Cell Cycle: In prokaryotes, the cell cycle is relatively simple and rapid. It involves a single round of DNA replication followed by binary fission. The entire process can take as little as 20 minutes in some bacteria.

Eukaryotic Cell Cycle: Eukaryotic cells have a more complex cell cycle that involves multiple stages of growth and division. The cycle is divided into two main phases: interphase and mitosis.

Interphase: This is the longest phase of the cell cycle, during which the cell grows and prepares for division. It is divided into three sub-phases: G₁, S, and G₂.

G₁ Phase: The cell grows in size and synthesizes proteins and organelles. It is the first phase of interphase.

S Phase: DNA replication occurs, resulting in the synthesis of a second copy of each chromosome. This phase is critical for ensuring that each daughter cell receives a complete set of genetic material.

G₂ Phase: The cell continues to grow and prepares for the upcoming mitosis. It is the final phase of interphase.

Mitosis: This is the phase of the cell cycle where the cell divides its genetic material and cytoplasm to produce two daughter cells. It is a highly regulated process that involves the coordinated action of various proteins and signaling pathways.

Prokaryotic Mitosis: In prokaryotes, mitosis is a simple process that involves the replication of the single circular chromosome and the division of the cell into two daughter cells.

Eukaryotic Mitosis: Eukaryotic mitosis is a more complex process that involves the replication of multiple linear chromosomes and the division of the cell into two daughter cells. It is divided into four main stages: prophase, metaphase, anaphase, and telophase.

Cell Cycle Regulation: The cell cycle is tightly regulated by a complex network of proteins and signaling pathways. Key regulatory proteins include cyclins and cyclin-dependent kinases (CDKs).

Checkpoints: These are points in the cell cycle where the cell can pause or stop the cycle if there are problems with the DNA or the cell's internal state. Checkpoints ensure that the cell only divides when it is ready and that the genetic material is accurate.

Cell Cycle and Cancer: Dysregulation of the cell cycle can lead to cancer. Mutations in the genes that control the cell cycle can cause cells to divide uncontrollably, leading to the formation of tumors.

Cell Cycle and Aging: The cell cycle is also involved in the process of aging. As cells age, they may experience changes in the regulation of the cell cycle, leading to a decline in cell function and the development of age-related diseases.

Cell Cycle and Development: The cell cycle plays a crucial role in the development of an organism. It is responsible for the growth and differentiation of cells, which are essential for the formation of tissues and organs.

Cell Cycle and Disease: In addition to cancer, the cell cycle is also involved in other diseases. For example, defects in the cell cycle can lead to developmental disorders and neurodegenerative diseases.

Phase	Prokaryotic	Eukaryotic	Duration (min)	Key Events
G ₁	~20	~40-60	~20-40	Cell growth, protein synthesis
S	~20	~30-40	~20-30	DNA replication
G ₂	~20	~20-30	~20-30	Cell growth, protein synthesis
M	~20	~10-20	~10-20	Chromosome segregation, cell division
