

Structural Role of cartilage is to absorb shock, supporting the underlying bony structure. It is found in the intervertebral discs, the articular surfaces of the joints, and the menisci of the knee. It is also found in the epiphyseal plates of the long bones, where it allows for growth. It is also found in the ear, where it provides support and flexibility.

Types of cartilage include hyaline cartilage, fibrocartilage, and elastic cartilage. Hyaline cartilage is the most common type and is found in the joints, the nose, and the trachea. Fibrocartilage is found in the intervertebral discs and the menisci of the knee. Elastic cartilage is found in the ear and the epiglottis. **Articular cartilage** is a type of hyaline cartilage that covers the ends of bones in the joints. It is composed of a dense network of collagen fibers and proteoglycan molecules. It is highly resilient and can withstand significant mechanical stress. **Intervertebral discs** are composed of a central nucleus pulposus surrounded by an annulus fibrosus. The nucleus pulposus is a gelatinous substance that provides most of the disc's resistance to compression. The annulus fibrosus is a ring of fibrous tissue that surrounds the nucleus and provides structural support.

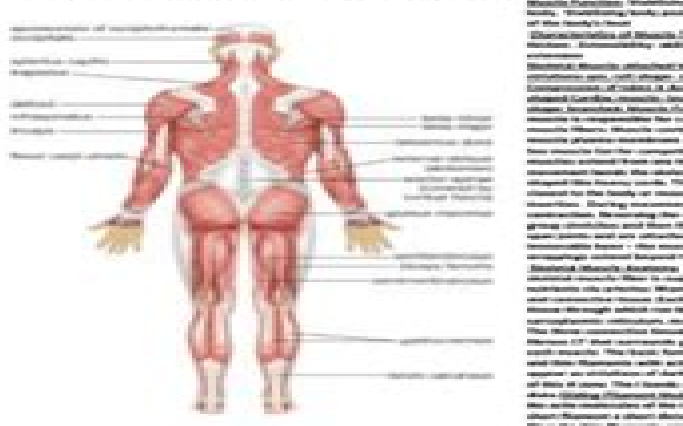

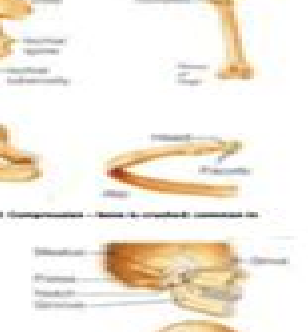

Development of long bones involves the process of endochondral ossification. It begins with a cartilaginous model of the bone, which is gradually replaced by bone tissue. The process involves the formation of a primary ossification center in the center of the shaft and secondary ossification centers at the ends. The epiphyseal plate, or growth plate, is a layer of cartilage that allows for longitudinal growth. It is composed of several layers of cells, including the zone of resting cartilage, the zone of proliferating cartilage, the zone of hypertrophying cartilage, the zone of calcified cartilage, and the zone of ossification. The zone of ossification is where the bone tissue is formed. The epiphyseal plate is highly vascularized and receives its blood supply from the epiphyseal vessels. It is also highly innervated and is sensitive to mechanical stress. The growth of the long bones continues until the epiphyseal plates have fused, which typically occurs by the age of 25.

Structural Role of long bones is to provide support and leverage for movement. They are composed of a central shaft (diaphysis) and two ends (epiphyses). The shaft is composed of compact bone tissue, which is highly resistant to bending and twisting. The epiphyses are composed of spongy bone tissue, which is lighter and more porous. The long bones are highly vascularized and receive their blood supply from the epiphyseal vessels. They are also highly innervated and are sensitive to mechanical stress. The long bones are essential for the support and movement of the body.

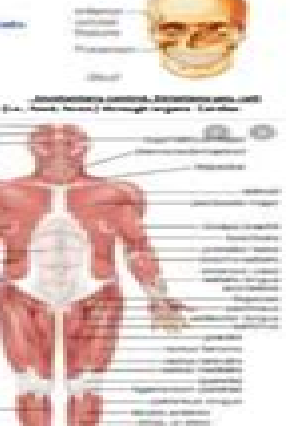

Structural Role of long bones is to provide support and leverage for movement. They are composed of a central shaft (diaphysis) and two ends (epiphyses). The shaft is composed of compact bone tissue, which is highly resistant to bending and twisting. The epiphyses are composed of spongy bone tissue, which is lighter and more porous. The shaft is composed of compact bone tissue, which is highly resistant to bending and twisting. The epiphyses are composed of spongy bone tissue, which is lighter and more porous. The long bones are highly vascularized and receive their blood supply from the epiphyseal vessels. They are also highly innervated and are sensitive to mechanical stress. The long bones are essential for the support and movement of the body.

Structural Role of muscles is to provide force for movement. They are composed of muscle fibers that are arranged in parallel. The muscle fibers are highly specialized for contraction and are capable of generating significant force. The muscles are highly vascularized and receive their blood supply from the epiphyseal vessels. They are also highly innervated and are sensitive to mechanical stress. The muscles are essential for the support and movement of the body.
