

The Digestive Process

The digestive system

The digestive system, or gastrointestinal tract, is essentially a muscular tube in which food is broken down by the action of enzymes and chemical substances. Food enters the mouth, is chewed, and is propelled through a series of different accessory and absorptive components. Within these components, food is digested (broken down) by digestive enzymes and components that absorb it. The digestive system also stores undigested components until they are ready to be expelled at the end of the gastrointestinal tract.

Ingestion

Chewing & swallowing

Chewing, the mechanical action of the mouth and tongue, begins the breakdown of solid food. This greatly increases food's surface area and exposes the food to the action of the salivary glands. Saliva contains the food and begins the digestion of starch. The mixture of food and saliva is called a *bolus*. In the bolus, the pharynx, the esophagus, a flap-like valve, and the vocal cord contract, forcing the bolus forward, where it moves into the esophagus for the stomach.

Peristaltic action

Material is moved through the digestive system by a series of muscle contractions called peristalsis. The muscle is relaxed at the material's entrance, while the muscle ahead contracts, forcing the material into the next section.

In the esophagus, material moves through the large intestine, where it is absorbed and eliminated. The remaining mass is moved forward and upward (retrograde).

Colonic movement

Movement through the large intestine is accomplished through the contractions of the longitudinal and circular muscles. Types of movement include peristaltic action, segmental action, and mass movement. Movement of food through the large intestine is slower than through the small intestine, allowing for reabsorption of water.

Types of movement

Segmentation action

In regular intervals, ring-like contractions (called segmentation) occur and mix the water material. This is the most common type of movement in the large intestine.
