Assembly of the Photosystem II Membrane-Protein Complex of Oxygenic Photosynthesis

Julian J. Eaton-Rye, Roman Sobotka, 2017-08-08 Photosystem II is a 700 kDa membrane protein super complex responsible for the light driven splitting of water in oxygenic photosynthesis The photosystem is comprised of two 350 kDa complexes each made of 20 different polypeptides and over 80 co factors While there have been major advances in understanding the mature structure of this photosystem many key protein factors involved in the assembly of the complex do not appear in the holoenzyme The mechanism for assembling this super complex is a very active area of research with newly discovered assembly factors and subcomplexes requiring characterization Additionally the ability to split water is inseparable from light induced photodamage that arises from radicals and reactive O₂ species generated by Photosystem II chemistry Consequently to sustain water splitting a self repair cycle has evolved whereby damaged protein is removed and replaced so as to extend the working life of the complex Understanding how the biogenesis and repair processes are coordinated is among several important questions that remain to be answered Other questions include how and when are the inorganic cofactors inserted during the assembly and repair processes and how are the subcomplexes protected from photodamage during assembly Evidence has also been obtained for Photosystem II biogenesis centers in cyanobacteria but do these also exist in plants Do the molecular mechanisms associated with Photosystem II assembly shed fresh light on the assembly of other major energy transducing complexes such as Photosystem I or the cytochrome b₆ f complex or indeed other respiratory complexes The contributions to this Frontiers in Plant Science Research Topic are likely to reveal new details applicable to the assembly of a range of membrane protein complexes including aspects of self assembly and solar energy conversion that may be applied to artificial photosynthetic systems In addition a deeper understanding of Photosystem II assembly particularly in response to changing environmental conditions will provide new knowledge underpinning photosynthetic yields which may contribute to improved food production and long term food security

Remodeling of cardiac passive electrical properties and susceptibility to ventricular and atrial arrhythmias George E. Billman, 2015-09-25 The effective management of cardiac arrhythmias either of atrial or of ventricular origin remains a major challenge Sudden cardiac death due to ventricular tachyarrhythmias remains the leading cause of death in industrialized countries while atrial fibrillation is the most common rhythm disorder an arrhythmia that s prevalence is increasing and accounts for nearly one quarter of ischemic strokes the elderly population Yet despite the enormity of the problem effective therapeutic interventions remain elusive In fact several initially promising antiarrhythmic agents were found to increase rather than decrease mortality in patients recovering from myocardial infarction The question then is what went wrong why have these interventions proven to be so ineffective An obvious answer is the drugs were designed to attack the wrong therapeutic target Clearly targeting single ion channels using either isolated ion channels or single myocytes preparations has proven to be less than effective What then is the appropriate target It is well established that cardiac electrical properties can vary substantially between single cells and intact preparations One obvious example is the observation that action potential duration is much longer in isolated cells as compared to multi cellular preparations or intact hearts Due to the low electrical resistance between adjacent myocytes the cells act in coordinated fashion producing electrotonic interdependence between neighboring cells Myocardial infarction and or acute ischemia provoke profound changes in the passive electrical properties of cardiac muscle In particular electrotonic uncoupling of the myocytes disrupts the coordinated activation and repolarization of cardiac tissue The resulting compensatory changes in ionic currents decrease cardiac electrical stability increasing the risk for life threatening changes in the cardiac rhythm Thus the electrical properties of myocardial cells must be considered as a unit rather than in isolation It is the purpose of this Research Topic to evaluate the largely neglected relationship between changes in passive electrical properties of cardiac muscle and arrhythmia formation *Report* Montana.
