

Chemically Formed Sedimentary Rocks – The chart shows three chemically formed sedimentary rocks: rock salt, rock gypsum and dolostone, having the texture of crystalline – a texture that shows crystals. Each one of them has different mineral compositions, but all are made by the evaporation of water. As water evaporates, the dissolved minerals become concentrated and start to precipitate (released) out of the water, settling to the bottom building an evaporite sedimentary rock. This is how salt layers are produced. In the Comments column, are the terms “precipitates and evaporites.”

Organically Formed Sedimentary Rocks – These rocks were formed from once living material, making a bioclastic or crystalline texture. Coal having a bioclastic texture is composed of carbon from the compaction of trees and plant remains. The other given example of a bioclastic or crystalline texture is limestone. The Comments section for limestone states “Precipitates of biologic origin or cemented shell fragments.” These substances contain the mineral calcite, which reacts by bubbling when in contact with hydrochloric acid. This is why an acid test is useful in identifying limestone.

Additional Information:

Breccia is a type of conglomerate. The difference between breccia and a conglomerate is that breccia shows angular fragments, while a conglomerate have mostly rounded sediments averaging greater than 0.2 mm in size.
