N. Popper, R. R. Fay, 2012-12-06. The past two decades have seen an extraordinary growth of interest in the auditory mechanisms of a wide range of vertebrates and invertebrates. Investigations have ranged from auditory mechanisms in relatively simple animals where just a few cells are employed for detection of sound to the highly complex detection and processing systems of man and the other mammals. Of particular significance to us has been the growing interest in general principles of vertebrate auditory system organization as opposed to a specific and limited concern for the mammalian or even

human systems Some of the interest in nonmammalian systems has risen from the desire to find simpler experimental models for both the essential components e.g. the hair cell receptor and the more complex functions e.g. frequency analysis of all vertebrate auditory systems Interest has also risen from questions about the evolution of hearing and the covariation or lack of it in structure and function in a wide variety of biological solutions to the problems of acoustic mechanoreception Of course the desire to find simpler experimental models and the need to answer questions about the evolution of hearing are not unrelated In fact detailed analyses of a variety of systems have led several times to the realization that some of the simple systems are more complex than initially thought
