

CHAPTER 1

6. Name the cells that undergo meiosis in a bisexual flower

Microspore mother cell to produce haploid microspores (pollen grains)

Megaspore mother cell to produce haploid megaspores (embryo sac)

7. What is filiform apparatus? What is its significance?

The synergists have special cellular thickenings at the micropylar end called filiform apparatus. It plays an important role in guiding pollen tube into embryo sac through synergist.

8. Name the male and female gametophytes of angiosperms.

Male gametophyte is microspore or pollen grain. Female gametophyte is embryo sac.

9. Mention the advantage and disadvantage of cleistogamous flowers.

Cleistogamous flowers undergo autogamy as there is an assured seed set but the continued self-pollination leads to inbreeding depression.

10. What is pericarp? Give examples.

The remnants of persistent nucellus in a seed are called pericarp.

Eg. Nymphs, black pepper and berriest.

11. Why do you think the zygote is dormant for some time in a fertilised ovule?

The zygote remains dormant for some time in a fertilised ovule and divides only after certain amount of endosperm is formed from PEN, because the zygote requires reserve food materials of endosperm for the nutrition of the developing embryo.

12. Why does the zygote begin to divide only after the division of primary endosperm cell?

The zygote needs nourishment during its development as the mature, fertilised embryo sac offers little nourishment to the zygote. So, the primary endosperm cell divides and generates the endosperm tissue which nourishes the zygote. Hence the zygote always divides after the division of primary endosperm cell.

13. Differentiate between the following.

Microcotyl	Spiny
The cylindrical portion of the endosperm axis below the level of cotyledon is called hypocotyl that terminates in radical.	The portion of the embryonic axis above the level of cotyledon is called epicotyl that terminates in plumule.
Coleoptile	Epicotyle
In monocot seeds, plumule is covered by a protective sheath called coleoptile.	In monocot seeds, radical and root cap are covered by a protective sheath called coleorhiza.
Integument	Testa
The protective covering of the ovule is called integument.	The outer protective seed layer is called testa.
Perisperm	Pericarp
The remnants of persistent nucellus in a seed are called perisperm.	The wall of ripened ovary or fruit is called pericarp.

CHAPTER 2

14. What are false fruits? Give example.

The fruits developed from the floral parts other than the ovary are called false fruits. Eg. Apple, Strawberry, cashew, etc. In these fruits, the thalamus forms into the edible part.

15. What are parthenocarpic fruits? Give example.

The fruits developed from unfertilised ovary are called parthenocarpic fruits. They are seedless fruits. It can be induced by the application of growth hormones. Eg. Banana, grapes, etc.

16. Why apple is called a false fruit? Which part of the flower forms the fruit?

The fruits developed from the parts other than the ovary are called false fruits. Apple is called so because the thalamus forms the edible part of the apple.

Figure 2.1: Development of an apple fruit.

17. If one can induce parthenocarpy through the application of growth substances, which fruit would you select to use parthenocarpy and why?

Parthenocarpy can be induced in banana, grapes and guava to obtain seedless fruits.

18. Are pollination and fertilisation necessary in apomixis? Give reasons.

Pollination and fertilisation are not necessary because in apomixis, the embryos develop directly from the cells of nucellus, integument or megaspore mother cell.

19. Embryo sacs of some apomictic species appear normal but contain diploid cells. Why?

It is true that many apomictic species possess normal looking embryo sacs. The only possibility of the embryo sac possessing diploid cells is due to failure of meiotic division of megaspore mother cell. The MII undergoes mitosis instead of meiosis to produce all diploid cells.

20. Can an unfertilised, apomictic embryo sac give rise to a diploid embryo? If yes, How?

Yes, if the embryo develops from the cells of nucellus or integument as they are diploid.

21. Name the mechanism responsible for the formation of seed without fertilisation in angiosperms. Give an example.

Apomixis. Eg. grasses and members of Asteraceae.

22. Are parthenocarpy and apomixis different phenomena?

Parthenocarpy and apomixis are different phenomena. Parthenocarpy is the formation of fruits without fertilisation and hence the fruits are seedless. Whereas, apomixis is the phenomenon of formation of seeds without fertilisation. These embryos are genetically identical to the parental plant.
