using individual masks for each foot strike Producing a 54 subject database from which the normal behavior of the foot could be quantified The group showed a surprisingly low right foot step off dominance of only 54% The combination of the radius of gyration and impulse in particular produces a succinct but powerful summary of the footprint during dynamic activity The initial angle and magnitudes of the loads that are applied and removed demonstrates that the body first rocks onto the heels after the instruction to walk is given The feet simultaneously invert and their arches rise off the ground as anticipated The principle axes were then animated in a mathematical four dimensional model The horizontal radius of gyration is on average 5 cm during heel strike but increases to 20 cm as the forefoot comes into contact with the ground finally rising to 25 cm at toe off Significantly the applied load during the fore foot loading phase is more widely distributed than the load being removed A new and unanticipated result that is believed to be a special characteristic of the animate foot The standard deviation of the force under the great toe is the first mechanical parameter to converge in the 54 subjects conclusively verifying the hypothesis that the great toe both initiates and controls gait
