Kinter, 2013-09-17 A key experiment in biomedical research is monitoring the expression of different proteins in order to detect changes that occur in biological systems under different experimental conditions The method that is most widely used is the Western blot analysis While Western blot is a workhorse in laboratories studying protein expression and has several advantages it also has a number of significant limitations In particular the method is semi quantitative with limited dynamic range Western blot focuses on a single protein per sample with only a small number of representative samples analyzed in an experiment New quantitative tools have been needed for some time to at least supplement possibly replace the Western blot Mass spectrometric methods have begun to compete with Western blot for routine quantitative analyses of proteins One of these methods is based on the tandem mass spectrometry technique of selected reaction monitoring SRM which is also called multiple reaction monitoring MRM Selected reaction monitoring is actually an older tandem mass spectrometry technique first described in the late 70s that is widely utilized in the quantitative analysis of small molecules like drugs metabolites The use of selected reaction monitoring for the quantitative analysis of

proteins has a number of advantages Most importantly it is fundamentally quantitative with a wide dynamic range The output of the analysis is a numerical result that can range over several orders of magnitude Other advantages include sufficient specificity sensitivity to detect low abundance proteins in complex mixtures Finally selected reaction monitoring can be multiplexed to allow the quantitative analysis of relatively large numbers of proteins in a single sample in a single experiment This Brief will explain both the theoretical experimental details of the selected reaction monitoring experiment as it is applied to proteins
