Predicting Breeding Values with Applications in Forest Tree Improvement T.L. White, G.R. Hodge, 2013-03-09 In most breeding programs of plant and animal species genetic data such as data from field progeny tests are used to rank parents and help choose candidates for selection In general all selection processes first rank the candidates using some function of the observed data and then choose as the selected portion those candidates with the largest or smallest values of that function To make maximum progress from selection it is necessary to use a function of the data that results in the candidates being ranked as closely as possible to the true but always unknown ranking Very often the observed data on various candidates are messy and unbalanced and this complicates the process of developing precise and accurate rankings For example for any given candidate there may be data on that candidate and its siblings growing in several field tests of different ages Also there may be performance data on siblings ancestors or other relatives from greenhouse laboratory or other field tests In addition data on different candidates may differ drastically in terms of quality and quantity available and may come from varied relatives Genetic improvement programs which make most effective use of these varied messy unbalanced and ancestral data will maximize progress from all stages of selection In this regard there are two analytical techniques best linear prediction BLP and best linear unbiased prediction BLUP which are quite well suited to predicting genetic values from a wide variety of sources ages qualities and quantities of data
